## Large-step operational semantics for IMP; Properties of IMP

## 1 Large-step operational semantics for IMP

We define large-step evaluation relations for arithmetic expressions, boolean expressions, and commands. The relation for arithmetic expressions relates an arithmetic expression and store to the integer value that the expression evaluates to. For boolean expressions, the final value is in Bool $=\{$ true, false $\}$. For commands, the final value is a store.

$$
\begin{aligned}
& \Downarrow_{\text {Aexp }} \subseteq \text { Aexp } \times \text { Store } \times \text { Int } \\
& \Downarrow_{\text {Bexp }} \subseteq \text { Bexp } \times \text { Store } \times \text { Bool } \\
& \Downarrow_{\text {Com }} \subseteq \text { Com } \times \text { Store } \times \text { Store }
\end{aligned}
$$

Again, we overload the symbol $\Downarrow$ and use it for any of these three relations; which relation is intended will be clear from context. We also use infix notation, for example writing $\langle c, \sigma\rangle \Downarrow \sigma^{\prime}$ if $\left(c, \sigma, \sigma^{\prime}\right) \in \Downarrow_{\mathrm{Com}}$. Arithmetic expressions.

$$
\begin{array}{cc}
\overline{\langle n, \sigma\rangle \Downarrow n} & \frac{\langle x, \sigma\rangle \Downarrow n}{} \text { where } \sigma(x)=n \\
\frac{\left\langle e_{1}, \sigma\right\rangle \Downarrow n_{1} \quad\left\langle e_{2}, \sigma\right\rangle \Downarrow n_{2}}{\left\langle e_{1}+e_{2}, \sigma\right\rangle \Downarrow n} \text { where } n=n_{1}+n_{2} & \frac{\left\langle e_{1}, \sigma\right\rangle \Downarrow n_{1} \quad\left\langle e_{2}, \sigma\right\rangle \Downarrow n_{2}}{\left\langle e_{1} \times e_{2}, \sigma\right\rangle \Downarrow n} \text { where } n=n_{1} \times n_{2}
\end{array}
$$

## Boolean expressions.

$$
\begin{array}{cc}
\hline\langle\text { true }, \sigma\rangle \Downarrow \text { true } & \langle\text { false }, \sigma\rangle \Downarrow \text { false } \\
\frac{\left\langle a_{1}, \sigma\right\rangle \Downarrow n_{1} \quad\left\langle a_{2}, \sigma\right\rangle \Downarrow n_{2}}{\left\langle a_{1}<a_{2}, \sigma\right\rangle \Downarrow \text { true }} \text { where } n_{1}<n_{2} & \frac{\left\langle a_{1}, \sigma\right\rangle \Downarrow n_{1} \quad\left\langle a_{2}, \sigma\right\rangle \Downarrow n_{2}}{\left\langle a_{1}<a_{2}, \sigma\right\rangle \Downarrow \text { false }} \text { where } n_{1} \geq n_{2}
\end{array}
$$

## Commands.

$$
\begin{aligned}
& \text { SKIP } \frac{\langle e, \sigma\rangle \Downarrow n}{\langle\mathbf{s k i p}, \sigma\rangle \Downarrow \sigma} \quad \text { ASG } \frac{\langle E Q}{\langle x:=e, \sigma\rangle \Downarrow \sigma[x \mapsto n]} \quad \operatorname{\langle c_{1},\sigma \rangle \Downarrow \sigma ^{\prime }}\left\langle\left\langle c_{2}, \sigma^{\prime}\right\rangle \Downarrow \sigma^{\prime \prime}\right) \\
& \text { If-T } \frac{\langle b, \sigma\rangle \Downarrow \text { true } \quad\left\langle c_{1}, \sigma\right\rangle \Downarrow \sigma^{\prime}}{\left\langle\text { if } b \text { then } c_{1} \text { else } c_{2}, \sigma\right\rangle \Downarrow \sigma^{\prime}} \quad \quad \operatorname{IF}-\mathrm{F} \frac{\langle b, \sigma\rangle \Downarrow \text { false } \quad\left\langle c_{2}, \sigma\right\rangle \Downarrow \sigma^{\prime}}{\left\langle\text { if } b \text { then } c_{1} \text { else } c_{2}, \sigma\right\rangle \Downarrow \sigma^{\prime}} \\
& \text { While-F } \frac{\langle b, \sigma\rangle \Downarrow \text { false }}{\langle\text { while } b \text { do } c, \sigma\rangle \Downarrow \sigma} \quad \text { While-T } \frac{\langle b, \sigma\rangle \Downarrow \text { true } \quad\langle c, \sigma\rangle \Downarrow \sigma^{\prime} \quad\left\langle\text { while } b \text { do } c, \sigma^{\prime}\right\rangle \Downarrow \sigma^{\prime \prime}}{\langle\text { while } b \text { do } c, \sigma\rangle \Downarrow \sigma^{\prime \prime}}
\end{aligned}
$$

It's interesting to see that the rule for while loops does not rely on using an if command (as we needed in the case of small-step semantics). Why does this rule work?

### 1.1 Command equivalence

The small-step operational semantics suggest that the loop while $b$ do $c$ should be equivalent to the command if $b$ then ( $c$; while $b$ do $c$ ) else skip. Can we show that this indeed the case that the language is defined using the above large-step evaluation?

First, we need to to be more precise about what "equivalent commands" mean. Our formal model allows us to define this concept using large-step evaluations as follows. (One can write a similar definition using $\longrightarrow *$ in small-step semantics.)

Definition (Equivalence of commands). Two commands $c$ and $c^{\prime}$ are equivalent (written $c \sim c^{\prime}$ ) if, for any stores $\sigma$ and $\sigma^{\prime}$, we have

$$
\langle c, \sigma\rangle \Downarrow \sigma^{\prime} \Longleftrightarrow\left\langle c^{\prime}, \sigma\right\rangle \Downarrow \sigma^{\prime} .
$$

We can now state and prove the claim that while $b$ do $c$ and if $b$ then ( $c$; while $b$ do $c$ ) else skip are equivalent.

Theorem. For all $b \in \operatorname{Bexp}$ and $c \in \operatorname{Com}$ we have

$$
\text { while } b \text { do } c \sim \text { if } b \text { then }(c ; \text { while } b \text { do } c) \text { else skip. }
$$

Proof. Let $W$ be an abbreviation for while $b$ do $c$. We want to show that for all stores $\sigma, \sigma^{\prime}$, we have:

$$
\langle W, \sigma\rangle \Downarrow \sigma^{\prime} \text { if and only if if } b \text { then }(c ; W) \text { else skip } \Downarrow \sigma^{\prime}
$$

For this, we must show that both directions $(\Longrightarrow$ and $\Longleftarrow$ ) hold. We'll show only direction $\Longrightarrow$; the other is similar.

Assume that $\sigma$ and $\sigma^{\prime}$ are stores such that $\langle W, \sigma\rangle \Downarrow \sigma^{\prime}$. It means that there is some derivation that proves for this fact. Inspecting the evaluation rules, we see that there are two possible rules whose conclusions match this fact: While-F and While-T. We analyze each of them in turn.

- While-F. The derivation must look like the following.

$$
\text { WHILE-F } \frac{\frac{\vdots 1}{\langle b, \sigma\rangle \Downarrow \text { false }}}{\langle W, \sigma\rangle \Downarrow \sigma}
$$

Here, we use : ${ }^{1}$ to refer to the derivation of $\langle b, \sigma\rangle \Downarrow$ false. Note that in this case, $\sigma^{\prime}=\sigma$.
We can use $:^{1}$ to derive a proof tree showing that the evaluation of if $b$ then $(c ; W)$ else skip yields the same final state $\sigma$ :

$$
\text { IF-F } \frac{\frac{\vdots_{1}}{\langle b, \sigma\rangle \Downarrow \text { false }} \quad \text { SKIP } \frac{}{\langle\text { if } b \text { then }(c ; W) \text { else skip }, \sigma\rangle \Downarrow \sigma}, \sigma \Downarrow \sigma}{\langle\text { skip }}
$$

- While-T. In this case, the derivation has the following form.

$$
\text { WHILE-T } \frac{\frac{\vdots 2}{\langle b, \sigma\rangle \Downarrow \text { true }} \quad \frac{\vdots}{\langle c, \sigma\rangle \Downarrow \sigma^{\prime \prime}}}{\langle W, \sigma\rangle \Downarrow \sigma^{\prime}} \frac{\vdots 4}{\left\langle W, \sigma^{\prime \prime}\right\rangle \Downarrow \sigma^{\prime}}
$$

We can use subderivations $::^{2},:_{3}$, and $:^{4}$ to show that the evaluation of if $b$ then $(c ; W)$ else skip yields the same final state $\sigma$.

$$
\text { IF-T } \frac{\frac{:^{2}}{\langle b, \sigma\rangle \Downarrow \text { true }} \quad \operatorname{SEQ} \frac{\frac{:^{3}}{\langle c, \sigma\rangle \Downarrow \sigma^{\prime \prime}} \quad \frac{: 4}{\left\langle W, \sigma^{\prime \prime}\right\rangle \Downarrow \sigma^{\prime}}}{\langle c ; W, \sigma\rangle \Downarrow \sigma^{\prime}}}{\langle\text { if } b \text { then }(c ; W) \text { else skip }, \sigma\rangle \Downarrow \sigma^{\prime}}
$$

Hence, we showed that in each of the two possible cases, the command if $b$ then $(c ; W)$ else skip evaluates to the same final state as the command $W$.

## 2 Some properties of IMP

### 2.1 Equivalence of semantics

The small-step and large-step semantics are equivalent. We state this formally in the following theorem.
Theorem (Equivalence of IMP semantics). For all commands $c \in \operatorname{Com}$ and stores $\sigma, \sigma^{\prime} \in$ Store we have

$$
\langle c, \sigma\rangle \longrightarrow^{*}\left\langle\mathbf{s k i p}, \sigma^{\prime}\right\rangle \Longleftrightarrow\langle c, \sigma\rangle \Downarrow \sigma^{\prime} .
$$

### 2.2 Non-termination

For a command $c$ and initial state $\sigma$, the execution of the command may terminate with some final store $\sigma^{\prime}$, or it may diverge and never yield a final state. For example, the command while true do foo $:=$ foo +1 always diverges; the command while $0<\mathrm{i}$ do $\mathrm{i}:=\mathrm{i}+1$ will diverge if and only if the value of variable i in the initial state is positive.

If $\langle c, \sigma\rangle$ is a configuration that diverges, then there is no state $\sigma$ such that $\langle c, \sigma\rangle \Downarrow \sigma^{\prime}$ or $\langle c, \sigma\rangle \longrightarrow^{*}$ $\left\langle\mathbf{s k i p}, \sigma^{\prime}\right\rangle$. However, in small-step semantics, a diverging computation has an infinite sequence of configurations: $\langle c, \sigma\rangle \longrightarrow\left\langle c_{1}, \sigma_{1}\right\rangle \longrightarrow\left\langle c_{2}, \sigma_{2}\right\rangle \longrightarrow \ldots$ Small-step semantics can allow us to state, and prove, properties about programs that may diverge. Later in the course, we will specify and prove properties that are of interest in potentially diverging computations.

### 2.3 Determinism of commands

The semantics of IMP (both small-step and large-step) are deterministic. That is, each IMP command $c$ and each initial store $\sigma$ evaluates to at most one final store. We state this formally for the large-step semantics below.

Theorem. For all commands $c \in$ Com and stores $\sigma, \sigma_{1}, \sigma_{2} \in$ Store, if $\langle c, \sigma\rangle \Downarrow \sigma_{1}$ and $\langle c, \sigma\rangle \Downarrow \sigma_{2}$ then $\sigma_{1}=\sigma_{2}$.
We need an inductive proof to prove this theorem. However, induction on the structure of command $c$ does not work. (Why? Which of the cases does it fail for?) Instead, we need to perform induction on the derivation of $\langle c, \sigma\rangle \Downarrow \sigma_{1}$. We first introduce some useful notation.

Let $d$ be a derivation. We write $d \Vdash y$ if $d$ is a derivation of $y$, that is, if the conclusion of $d$ is $y$. For example, if $d$ is the following deriviation

$$
\frac{\frac{\overline{\langle 6, \sigma\rangle \Downarrow 6} \quad \overline{\langle 7, \sigma\rangle \Downarrow 7}}{\langle 6 \times 7, \sigma\rangle \Downarrow 42}}{\langle\mathrm{i}:=6 \times 7, \sigma\rangle \Downarrow \sigma[\mathrm{i} \mapsto 42]}
$$

then we have $d \Vdash\langle\mathrm{i}:=42, \sigma\rangle \Downarrow \sigma[\mathrm{i} \mapsto 42]$.
We say that derivation $d$ has the form $\left\{d_{1}, \ldots, d_{n}\right\} / y$ if $d \Vdash y$ and the inference rule that $d$ used to conclue $y$ has premises $y_{1}, \ldots, y_{n}$ such that $d_{1} \Vdash y_{1}, \ldots, d_{n} \Vdash y_{n}$.

Let $d$ and $d^{\prime}$ be derivations. We say that $d^{\prime}$ is an immediate subderivation of $d$ if $d^{\prime}$ if $d$ is of the form $\left\{d^{\prime}, d_{1}, \ldots, d_{n}\right\} / y$. That is, $d^{\prime}$ is a derivation of one of the premises used in the final rule in the derivation $d$. For example, the derivation

$$
\frac{\overline{\langle 6, \sigma\rangle \Downarrow 6} \quad \overline{\langle 7, \sigma\rangle \Downarrow 7}}{\langle 6 \times 7, \sigma\rangle \Downarrow 42}
$$

is an immediate subderivation of

$$
\frac{\frac{\langle 6, \sigma\rangle \Downarrow 6}{\langle 6 \times 7, \sigma\rangle \Downarrow 42}}{\langle\mathrm{i}:=6 \times 7, \sigma\rangle \Downarrow \sigma[\mathrm{i} \mapsto 42]}
$$

Proof. We proceed by induction on the derivation of $\langle c, \sigma\rangle \Downarrow \sigma_{1}$. The inductive hypothesis $P$ is

$$
P(d)=\forall c \in \mathbf{C o m} . \forall \sigma, \sigma^{\prime}, \sigma^{\prime \prime} \in \text { Store, if }\langle c, \sigma\rangle \Downarrow \sigma^{\prime \prime} \text { and } d \Vdash\langle c, \sigma\rangle \Downarrow \sigma^{\prime} \text { then } \sigma^{\prime}=\sigma^{\prime \prime} .
$$

Let $d$ be a derivation. Assume that the inductive hypothesis holds for all immediate subderivations of $d$. Assume $\langle c, \sigma\rangle \Downarrow \sigma^{\prime \prime}$ and $d \Vdash\langle c, \sigma\rangle \Downarrow \sigma^{\prime}$. Since $\langle c, \sigma\rangle \Downarrow \sigma^{\prime \prime}$, there must be some derivation $d_{1}$ such that $d_{1} \Vdash\langle c, \sigma\rangle \Downarrow \sigma^{\prime \prime}$.

We consider the possible cases for the last rule used in derivation $d$.

- Skip

In this case

$$
d=\operatorname{SKIP} \frac{\vdots}{\langle\mathbf{s k i p}, \sigma\rangle \Downarrow \sigma},
$$

and we have $c=\mathbf{s k i p}$ and $\sigma^{\prime}=\sigma$. Since the rule SKIP is the only rule that has the command skip in its conclusion, the last rule used in $d_{1}$ must also be SKIP, and so we have $\sigma^{\prime \prime}=\sigma$ and the result holds.

- Asg

In this case

$$
d=\operatorname{ASG} \frac{\frac{\vdots}{\langle e, \sigma\rangle \Downarrow n}}{\langle x:=e, \sigma\rangle \Downarrow \sigma^{\prime}},
$$

and we have $c=x:=e$ and $\sigma^{\prime}=\sigma[x \mapsto n]$. The last rule used in $d_{1}$ must also be ASG, and so we have $\sigma^{\prime \prime}=\sigma^{\prime}$ and the result holds.

- Seq

In this case

$$
d=\operatorname{SEQ} \frac{\frac{\vdots}{\left\langle c_{1}, \sigma\right\rangle \Downarrow \sigma_{1}} \quad \frac{\vdots}{\left\langle c_{2}, \sigma_{1}\right\rangle \Downarrow \sigma^{\prime}}}{\left\langle c_{1} ; c_{2}, \sigma\right\rangle \Downarrow \sigma^{\prime}},
$$

and we have $c=c_{1} ; c_{2}$. The last rule used in $d_{1}$ must also be SEQ, and so we have

$$
d_{1}=\mathrm{SEQ} \frac{\frac{\vdots}{\left\langle c_{1}, \sigma\right\rangle \Downarrow \sigma_{1}^{\prime}} \quad \frac{\vdots}{\left\langle c_{2}, \sigma_{1}^{\prime}\right\rangle \Downarrow \sigma^{\prime \prime}}}{\left\langle c_{1} ; c_{2}, \sigma\right\rangle \Downarrow \sigma^{\prime \prime}} .
$$

By the inductive hypothesis applied to the derivation $\frac{\vdots}{\left\langle c_{1}, \sigma\right\rangle \Downarrow \sigma_{1}}$, we have $\sigma_{1}=\sigma_{1}^{\prime}$. By another application of the inductive hypothesis, to the derivation $\overline{\left\langle c_{2}, \sigma_{1}\right\rangle \Downarrow \sigma^{\prime}}$, we have $\sigma^{\prime}=\sigma^{\prime \prime}$ and the result holds.

- IF-T

Here we have

$$
d=\mathrm{IF-T} \frac{\frac{\vdots}{\langle b, \sigma\rangle \Downarrow \text { true }} \frac{\vdots}{\left\langle c_{1}, \sigma\right\rangle \Downarrow \sigma^{\prime}}}{\left\langle\text { if } b \text { then } c_{1} \text { else } c_{2}, \sigma\right\rangle \Downarrow \sigma^{\prime}},
$$

and we have $c=$ if $b$ then $c_{1}$ else $c_{2}$. The last rule used in $d_{1}$ must also be IF-T, and so we have

$$
d_{1}=\operatorname{IF-T} \frac{\frac{\vdots}{\langle b, \sigma\rangle \Downarrow \text { true }} \frac{\vdots}{\left\langle c_{1}, \sigma\right\rangle \Downarrow \sigma^{\prime \prime}}}{\left\langle\text { if } b \text { then } c_{1} \text { else } c_{2}, \sigma\right\rangle \Downarrow \sigma^{\prime \prime}} .
$$

The result holds by the inductive hypothesis applied to the derivation $\frac{\vdots}{\left\langle c_{1}, \sigma\right\rangle \Downarrow \sigma^{\prime \prime}}$.

- If-F

Similar to the case for IF-T.

- While-F

Straightforard, similar to the case for SKIP.

- While-T

Here we have

$$
d=\text { WHILE-T } \frac{\frac{\vdots}{\langle b, \sigma\rangle \Downarrow \text { true }} \frac{\vdots}{\left\langle c_{1}, \sigma\right\rangle \Downarrow \sigma_{1}} \frac{\vdots}{\left\langle c, \sigma_{1}\right\rangle \Downarrow \sigma^{\prime}}}{\left\langle\text { while } b \text { do } c_{1}, \sigma\right\rangle \Downarrow \sigma^{\prime}}
$$

and we have $c=$ while $b$ do $c_{1}$. The last rule used in $d_{1}$ must also be While-T, and so we have

$$
d_{1}=\text { WHILE-T } \frac{\frac{\vdots}{\langle b, \sigma\rangle \Downarrow \text { true }} \frac{\vdots}{\left\langle c_{1}, \sigma\right\rangle \Downarrow \sigma_{1}^{\prime}} \frac{\vdots}{\left\langle c, \sigma_{1}^{\prime}\right\rangle \Downarrow \sigma^{\prime \prime}}}{\left\langle\text { while } b \text { do } c_{1}, \sigma\right\rangle \Downarrow \sigma^{\prime \prime}} .
$$

By the inductive hypothesis applied to the derivation $\overline{\left\langle c_{1}, \sigma\right\rangle \Downarrow \sigma_{1}}$, we have $\sigma_{1}=\sigma_{1}^{\prime}$. By another application of the inductive hypothesis, to the derivation $\overline{\left\langle c, \sigma_{1}\right\rangle \Downarrow \sigma^{\prime}}$, we have $\sigma^{\prime}=\sigma^{\prime \prime}$ and the result holds.
Note: Even though the command $c=$ while $b$ do $c_{1}$ appears in the derivation $d$ of $\left\langle\mathbf{w h i l e} b\right.$ do $\left.c_{1}, \sigma\right\rangle \Downarrow$ $\sigma^{\prime}$, we do not run in to problems, as the induction is over the derivation, not over the structure of the command.

- For all rules for arithmetic expressions and boolean expressions (i.e., whose conclusion is of the form $\langle a, \sigma\rangle \Downarrow_{\text {Aexp }} n$ or $\langle b, \sigma\rangle \Downarrow_{\text {Bexp }} t$ ) the result is trivial, as it is not the case that $d \Vdash\langle c, \sigma\rangle \Downarrow \sigma^{\prime}$.
In all cases, we have shown that $\forall c \in \operatorname{Com} . \forall \sigma, \sigma^{\prime}, \sigma^{\prime \prime} \in \mathbf{S t o r e}$, if $\langle c, \sigma\rangle \Downarrow \sigma^{\prime \prime}$ and $d \Vdash\langle c, \sigma\rangle \Downarrow \sigma^{\prime}$ then $\sigma^{\prime}=\sigma^{\prime \prime}$. Thus we can conclude that $P(d)$ holds for all deriations for the executions of commands. This is equivalent to

$$
\forall c \in \text { Com. } \forall \sigma, \sigma^{\prime}, \sigma^{\prime \prime} \in \text { Store, if }\langle c, \sigma\rangle \Downarrow \sigma^{\prime} \text { and }\langle c, \sigma\rangle \Downarrow \sigma^{\prime \prime} \text { then } \sigma^{\prime}=\sigma^{\prime \prime}
$$

which proves the theorem.
