## 1 More types

We have previously explored the dynamic semantics of a number of language features. Here, we consider how to extend the type system of lambda calculus for some of the language features we saw previously, and some new ones.

### 1.1 Product and sums

We have previously seen products, which are pairs of expressions. Products were constructed using the expression $\left(e_{1}, e_{2}\right)$, and destructed using projection $\# 1 e$ and $\# 2 e$.

In addition to the structural rules, there are two operational semantics rules that show how the destructors and constructor interact.
$\overline{\# 1\left(v_{1}, v_{2}\right) \longrightarrow v_{1}}$

$$
\# 2\left(v_{1}, v_{2}\right) \longrightarrow v_{2}
$$

The type of a product expression (or a product type) is a pair of types, written $\tau_{1} \times \tau_{2}$. The typing rules for the product constructors and destructors are the following.

$$
\frac{\Gamma \vdash e_{1}: \tau_{1} \quad \Gamma \vdash e_{2}: \tau_{2}}{\Gamma \vdash\left(e_{1}, e_{2}\right): \tau_{1} \times \tau_{2}} \quad \frac{\Gamma \vdash e: \tau_{1} \times \tau_{2}}{\Gamma \vdash \# 1 e: \tau_{1}} \quad \frac{\Gamma \vdash e: \tau_{1} \times \tau_{2}}{\Gamma \vdash \# 2 e: \tau_{2}}
$$

We introduce sums, which are dual to products. Intuitively, a product holds two values, one of type $\tau_{1}$, and one of type $\tau_{2}$. By contrast, a sum holds a single value that is either of type $\tau_{1}$ or of type $\tau_{2}$. The type of a sum is written $\tau_{1}+\tau_{2}$. There are two constructors for a sum, corresponding to whether we are constructing a sum with a value of $\tau_{1}$ or a value of $\tau_{2}$.

$$
\begin{aligned}
& e::=\cdots\left|\operatorname{inl}_{\tau_{1}+\tau_{2}} e\right| \operatorname{inr}_{\tau_{1}+\tau_{2}} e \mid \text { case } e_{1} \text { of } e_{2} \mid e_{3} \\
& v::=\cdots\left|\operatorname{inl}_{\tau_{1}+\tau_{2}} v\right| \operatorname{inr}_{\tau_{1}+\tau_{2}} v
\end{aligned}
$$

Again, there are structural rules to determine the order of evaluation. In a CBV lambda calculus, the evaluation contexts are extended as follows.

$$
E::=\cdots\left|\operatorname{inl}_{\tau_{1}+\tau_{2}} E\right| \operatorname{inr}_{\tau_{1}+\tau_{2}} E \mid \text { case } E \text { of } e_{2} \mid e_{3}
$$

In addition to the structural rules, there are two operational semantics rules that show how the destructors and constructors interact.

$$
\text { case inl } \tau_{\tau_{1}+\tau_{2}} v \text { of } e_{2} \mid e_{3} \longrightarrow e_{2} v \quad \text { case } \operatorname{inr}_{\tau_{1}+\tau_{2}} v \text { of } e_{2} \mid e_{3} \longrightarrow e_{3} v
$$

The type of a sum expression (or a sum type) is written $\tau_{1}+\tau_{2}$. The typing rules for the sum constructors and destructor are the following.
$\frac{\Gamma \vdash e: \tau_{1}}{\Gamma \vdash \operatorname{inl}_{\tau_{1}+\tau_{2}} e: \tau_{1}+\tau_{2}} \quad \frac{\Gamma \vdash e: \tau_{2}}{\Gamma \vdash \inf _{\tau_{1}+\tau_{2}} e: \tau_{1}+\tau_{2}} \quad \frac{\Gamma \vdash e: \tau_{1}+\tau_{2} \quad \Gamma \vdash e_{1}: \tau_{1} \rightarrow \tau \quad \Gamma \vdash e_{2}: \tau_{2} \rightarrow \tau}{\Gamma \vdash \operatorname{case} e \text { of } e_{1} \mid e_{2}: \tau}$

Let's see an example of a program that uses sum types.

$$
\begin{aligned}
& \text { let } f:(\text { int }+(\text { int } \rightarrow \mathbf{i n t})) \rightarrow \text { int }= \\
& \qquad \lambda a: \text { int }+(\text { int } \rightarrow \text { int }) . \text { case } a \text { of } \lambda y . y+1 \mid \lambda g . g 35 \text { in } \\
& \text { let } h: \text { int } \rightarrow \text { int }=\lambda x: \text { int. } x+7 \text { in } \\
& f\left(\text { inr }_{\text {int }+(\text { int } \rightarrow \text { int })} h\right)
\end{aligned}
$$

Here, the function $f$ takes argument $a$, which is a sum. That is, the actual argument for $a$ will either be a value of type int or a value of type int $\rightarrow$ int. We destroy the sum value with a case statement, which must be prepared to take either of the two kinds of values that the sum may contain. We end up applying $f$ to a value of type int $\rightarrow$ int (i.e., a value injected into the right type of the sum). The entire program ends up evaluating to 42.

### 1.2 Recursion

We saw in last lecture that we could not type recursive functions or fixed-point combinators in the simplytyped lambda calculus. So instead of trying (and failing) to define a fixed-point combinator in the simplytyped lambda calculus, we add a new primitive fix to the language. The evaluation rules for the new primitive will mimic the behavior of fixed-point combinators.

We extend the syntax with the new primitive operator. Intuitively, fix $e$ is the fixed-point of the function $e$. Note that $\mathrm{fix} v$ is not a value.

$$
e::=\cdots \mid \text { fix } e
$$

We extend the operational semantics for the new operator. There is a new evaluation context, and a new axiom.

$$
E::=\cdots \mid \text { fix } E \quad \text { fix } \lambda x: \tau . e \longrightarrow e\{(\operatorname{fix} \lambda x: \tau . e) / x\}
$$

Note that we can define the letrec $x: \tau=e_{1}$ in $e_{2}$ construct in terms of the fix operator.

$$
\text { letrec } x: \tau=e_{1} \text { in } e_{2} \triangleq \text { let } x: \tau=\text { fix } \lambda x: \tau . e_{1} \text { in } e_{2}
$$

We add a new typing rule for the new language construct.

$$
\begin{gathered}
\Gamma \vdash e: \tau \rightarrow \tau \\
\Gamma \vdash \mathrm{fix} e: \tau
\end{gathered}
$$

Returning to our trusty factorial example, the following program implements the factorial function using the fix operator.

$$
F A C T \triangleq \operatorname{fix} \lambda f: \text { int } \rightarrow \text { int. } \lambda n \text { :int. if } n=0 \text { then } 0 \text { else } n \times(f(n-1))
$$

Or using our convenient letrec notation, we could define a variable fact as follows.

$$
\begin{aligned}
& \text { letrec } \text { fact: int } \rightarrow \text { int }=\lambda n \text { :int. if } n=0 \text { then } 0 \text { else } n \times(\text { fact }(n-1)) \\
& \text { in } \ldots
\end{aligned}
$$

We can write non-terminating computations for any type: the expression fix $\lambda x: \tau$. $x$ has type $\tau$, and does not terminate

Although the fix operator is normally used to define recursive functions, it can be used to find fixed
points of any type. For example, consider the following expression.

$$
\begin{aligned}
\text { fix } \lambda x:(\text { int } \rightarrow \text { int }) \times(\text { int } \rightarrow \text { int }) .(\lambda n: \text { int. if } n & =0 \text { then true else not }((\# 2 x)(n-1)), \\
\lambda n: \text { int. if } n & =0 \text { then false else not }((\# 1 x)(n-1)))
\end{aligned}
$$

This expression has type $($ int $\rightarrow \mathbf{i n t}) \times($ int $\rightarrow \mathbf{i n t})$-it is a pair of mutually recursive functions; the first function returns true if and only if its argument is even; the second function returns true if and only if its argument is odd.

### 1.3 References

Recall the syntax and semantics for references.

```
\(e::=\cdots \mid\) ref \(e|!e| e_{1}:=e_{2} \mid \ell\)
\(v::=\cdots \mid \ell\)
\(E::=\cdots \mid\) ref \(E|!E| E:=e \mid v:=E\)
```

$\operatorname{ALLOC} \overline{\langle\operatorname{ref} v, \sigma\rangle \longrightarrow\langle\ell, \sigma[\ell \mapsto v]\rangle} \ell \notin \operatorname{dom}(\sigma) \quad$ DEREF $\overline{\langle!\ell, \sigma\rangle \longrightarrow\langle v, \sigma\rangle} \sigma(\ell)=v$

$$
\text { AssIGN } \overline{\langle\ell:=v, \sigma\rangle \longrightarrow\langle v, \sigma[\ell \mapsto v]\rangle}
$$

We add a new type for references: type $\tau$ ref is the type of a location that contains a value of type $\tau$. For example the expression ref 7 has type int ref, since it evaluates to a location that contains a value of type int. Dereferencing a location of type $\tau$ ref results in a value of type $\tau$, so !e has type $\tau$ if $e$ has type $\tau$ ref. And for assignment $e_{1}:=e_{2}$, if $e_{1}$ has type $\tau$ ref, then $e_{2}$ must have type $\tau$.

Noticeable by its absence is a typing rule for location values. What is the type of a location value $\ell$ ? Clearly, it should be of type $\tau$ ref, where $\tau$ is the type of the value contained in location $\ell$. But how do
we know what value is contained in location $\ell$ ? We could directly examine the store, but that would be inefficient. In addition, examine the store directly may not give us a conclusive answer! Consider, for example, a store $\sigma$ and location $\ell$ where $\sigma(\ell)=\ell$; what is the type of $\ell$ ?

Instead, we introduce store typings to track the types of values stored in locations. Store typings are partial functions from locations to types. We use metavariable $\Sigma$ to range over store typings. Our typing relation now becomes a relation over 4 entities: typing contexts, store typings, expressions, and types. We write $\Gamma, \Sigma \vdash e: \tau$ when expression $e$ has type $\tau$ under typing context $\Gamma$ and store typing $\Sigma$.

Our new typing rules for references are as follows. (Typing rules for other constructs are modified to take a store typing in the obvious way.)
$\frac{\Gamma, \Sigma \vdash e: \tau}{\Gamma, \Sigma \vdash \operatorname{ref} e: \tau \text { ref }} \quad \frac{\Gamma, \Sigma \vdash e: \tau \text { ref }}{\Gamma, \Sigma \vdash!e: \tau} \quad \frac{\Gamma, \Sigma \vdash e_{1}: \tau \text { ref } \Gamma, \Sigma \vdash e_{2}: \tau}{\Gamma, \Sigma \vdash e_{1}:=e_{2}: \tau} \quad \frac{}{\Gamma, \Sigma \vdash \ell: \tau} \Sigma(\ell)=\tau$ ref

So, how do we state type soundness? Our type soundness theorem for simply-typed lambda calculus said that if $\Gamma \vdash e: \tau$ and $e \longrightarrow^{*} e^{\prime}$ then $e^{\prime}$ is not stuck. But our operational semantics for references now has a store, and our typing judgment now has a store typing in addition to a typing context. We need to adapt the definition of type soundness appropriately. to do so, we define what it means for a store to be well-typed with respect to a typing context.

Definition. Store $\sigma$ is well-typed with respect to typing context $\Gamma$ and store typing $\Sigma$, written $\Gamma, \Sigma \vdash \sigma$, if $\operatorname{dom}(\sigma)=\operatorname{dom}(\Sigma)$ and for all $\ell \in \operatorname{dom}(\sigma)$ we have $\Gamma, \Sigma \vdash \sigma(\ell): \Sigma(\ell)$.

We can now state type soundness for our language with references.

Theorem (Type soundness). If $\Gamma, \Sigma \vdash e: \tau$ and $\Gamma, \Sigma \vdash \sigma$ and $\langle e, \sigma\rangle \longrightarrow^{*}\left\langle e^{\prime}, \sigma^{\prime}\right\rangle$ then either $e^{\prime}$ is a value, or there exists $e^{\prime \prime}$ and $\sigma^{\prime \prime}$ such that $\left\langle e^{\prime}, \sigma^{\prime}\right\rangle \longrightarrow\left\langle e^{\prime \prime}, \sigma^{\prime \prime}\right\rangle$.

We can prove type soundness for our language using the same strategy as for the simply-typed lambda calculus: we use preservation and progress. The progress lemma can be easily adapted for the semantics and type system for references. Adapting preservation is a little more involved, since we need to describe how the store typing changes as the store evolves. The rule ALLOC extends the store $\sigma$ with a fresh location $\ell$, producing store $\sigma^{\prime}$. Since $\operatorname{dom}(\Sigma)=\operatorname{dom}(\sigma) \neq \operatorname{dom}\left(\sigma^{\prime}\right)$, it means that we will not have $\sigma^{\prime}$ well-typed with respect to typing store $\Sigma$.

Since the store can increase in size during the evaluation of the program, we also need to allow the store typing to grow as well.

Lemma (Preservation). If $\Gamma, \Sigma \vdash e: \tau$ and $\Gamma, \Sigma \vdash \sigma$ and $\langle e, \sigma\rangle \longrightarrow\left\langle e^{\prime}, \sigma^{\prime}\right\rangle$ then there exists some $\Sigma^{\prime} \supseteq \Sigma$ such that $\Gamma, \Sigma^{\prime} \vdash e^{\prime}: \tau$ and $\Gamma, \Sigma^{\prime} \vdash \sigma^{\prime}$.

We write $\Sigma^{\prime} \supseteq \Sigma$ to mean that for all $\ell \in \operatorname{dom}(\Sigma)$ we have $\Sigma(\ell)=\Sigma^{\prime}(\ell)$. This makes sense if we think of partial functions as sets of pairs: $\Sigma \equiv\{(\ell, v) \mid \ell \in \operatorname{dom}(\Sigma) \wedge \Sigma(\ell)=v\}$.

Note that the preservation lemma states simply that there is some store type $\Sigma^{\prime} \supseteq \Sigma$, but does not specify what exactly that store typing is. Intuitively, $\Sigma^{\prime}$ will either be $\Sigma$, or $\Sigma$ extended on a single, newly allocated, location.
