Today, we will learn about

 typing extensions to the simply-typed lambda-calculus

Products	
Syntax:	
	(e_1, e_2)
	#1 e
	#2 e

Context:

$$E ::= \ldots | (E, e) | (v, E) | #1 E | #2 E$$

Operational semantic rules:

$$\#1 (v_1, v_2) \longrightarrow v_1 \qquad \#2 (v_1, v_2) \longrightarrow v_2$$

Typing of Products

Product type: $\tau_1 \times \tau_2$ Typing rules:

 $\frac{\Gamma \vdash e_1 : \tau_1 \quad \Gamma \vdash e_2 : \tau_2}{\Gamma \vdash (e_1, e_2) : \tau_1 \times \tau_2}$

 $\frac{\Gamma \vdash e: \tau_1 \times \tau_2}{\Gamma \vdash \#1 \; e: \tau_1} \qquad \frac{\Gamma \vdash e: \tau_1 \times \tau_2}{\Gamma \vdash \#2 \; e: \tau_2}$

Sums Syntax:

$$e ::= \cdots | \operatorname{inl}_{\tau_1 + \tau_2} e | \operatorname{inr}_{\tau_1 + \tau_2} e | \operatorname{case} e_1 \operatorname{of} e_2 | e_3$$
$$v ::= \cdots | \operatorname{inl}_{\tau_1 + \tau_2} v | \operatorname{inr}_{\tau_1 + \tau_2} v$$

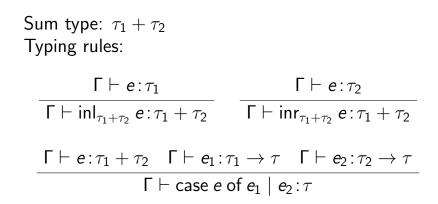

Context:

 $E ::= \cdots | \operatorname{inl}_{\tau_1 + \tau_2} E | \operatorname{inr}_{\tau_1 + \tau_2} E | \operatorname{case} E \operatorname{of} e_2 | e_3$ Operational rules:

case
$$\mathsf{inl}_{\tau_1+\tau_2} \mathsf{v} ext{ of } e_2 \mid e_3 \longrightarrow e_2 \mathsf{v}$$

case $\operatorname{inr}_{\tau_1+\tau_2} v$ of $e_2 \mid e_3 \longrightarrow e_3 v$

Typing of Sums

Example Program

$$\begin{array}{l} \operatorname{let} f:(\operatorname{int}+(\operatorname{int}\to\operatorname{int}))\to\operatorname{int}=\\ \lambda a:\operatorname{int}+(\operatorname{int}\to\operatorname{int}).\\ \operatorname{case} a \operatorname{of} \lambda y.\,y+1 \mid \lambda g.\,g \text{ 35 in} \\ \operatorname{let} h:\operatorname{int}\to\operatorname{int}=\lambda x:\operatorname{int}.\,x+7 \text{ in} \\ f \ (\operatorname{inr}_{\operatorname{int}+(\operatorname{int}\to\operatorname{int})}h) \end{array}$$

Recursion

We saw in last lecture that we could not type recursive functions or fixed-point combinators in the simply-typed lambda calculus. So instead of trying (and failing) to define a fixed-point combinator in the simply-typed lambda calculus, we add a new primitive $\mu x: \tau$. *e* to the language. The evaluation rules for the new primitive will mimic the behavior of fixed-point combinators.

Recursion: Syntax

$$e ::= \cdots \mid \mu x : \tau. e$$

Intuitively, $\mu x: \tau$. *e* is the fixed-point of the function $\lambda x: \tau$. *e*. Note that $\mu x: \tau$. *e* is *not* a value, regardless of whether *e* is a value or not.

Recursion: Operational Semantics

There is a new axiom, but no new evaluation contexts.

$$\mu x: \tau. \ e \longrightarrow e\{(\mu x: \tau. \ e)/x\}$$

Note that we can define the letrec $x: \tau = e_1$ in e_2 construct in terms of this new expression.

letrec
$$x: \tau = e_1$$
 in $e_2 \triangleq$ let $x: \tau = \mu x: \tau$. e_1 in e_2

Recursion: Typing

$\frac{\Gamma[x \mapsto \tau] \vdash e:\tau}{\Gamma \vdash \mu x:\tau. \ e:\tau}$

Example Program

$$FACT \triangleq \mu f : \mathbf{int} \to \mathbf{int}.$$

 $\lambda n : \mathbf{int}.$ if $n = 0$ then 1 else $n \times (f(n-1))$

letrec fact: int \rightarrow int = λn : int. if n = 0 then 1 else $n \times (fact (n - 1))$ in ...

Non-termination?

Recall operational semantics:

$$\mu x: \tau. \ e \longrightarrow e\{(\mu x: \tau. \ e)/x\}$$

Recall typing:

$$\frac{\Gamma[x \mapsto \tau] \vdash e:\tau}{\Gamma \vdash \mu x:\tau. \ e:\tau}$$

We can write non-terminating computations for any type: the expression $\mu x: \tau$. x has type τ , and does not terminate.

Although the $\mu x: \tau$. *e* expression is normally used to define recursive functions, it can be used to find fixed points of any type. For example, consider the following expression.

 $\mu x: (\mathbf{int} \to \mathbf{bool}) \times (\mathbf{int} \to \mathbf{bool}).$ $(\lambda n: \mathbf{int.} \text{ if } n = 0 \text{ then true else } ((\#2 \ x) \ (n-1)),$ $\lambda n: \mathbf{int.} \text{ if } n = 0 \text{ then false else } ((\#1 \ x) \ (n-1)))$

This expression has type $(int \rightarrow bool) \times (int \rightarrow bool)$ —it is a pair of mutually recursive functions; the first function returns true only if its argument is even; the second function returns true only if its argument is odd.

References: Syntax and Semantics

$$e ::= \cdots \mid \mathsf{ref} \ e \mid !e \mid e_1 := e_2 \mid \ell$$
$$v ::= \cdots \mid \ell$$
$$E ::= \cdots \mid \mathsf{ref} \ E \mid !E \mid E := e \mid v := E$$

$$\operatorname{ALLOC} - \operatorname{\mathsf{ref}} \mathbf{v}, \sigma > \longrightarrow < \ell, \sigma[\ell \mapsto \mathbf{v}] > \ell \notin \operatorname{\mathsf{dom}}(\sigma)$$

DEREF
$$- \langle !\ell, \sigma \rangle \rightarrow \langle v, \sigma \rangle \sigma(\ell) = v$$

Assign $- \langle \ell := \mathbf{v}, \sigma \rangle \longrightarrow \langle \mathbf{v}, \sigma[\ell \mapsto \mathbf{v}] \rangle$

Reference Type τ ref

- We add a new type for references: type τ ref is the type of a location that contains a value of type τ.
- For example the expression ref 7 has type int ref, since it evaluates to a location that contains a value of type int.
- Dereferencing a location of type τ ref results in a value of type τ, so !e has type τ if e has type τ ref.
- And for assignment e₁ := e₂, if e₁ has type τ ref, then e₂ must have type τ.

References: Typing

 $\mathsf{\Gamma} \vdash \mathsf{e}_1 := \mathsf{e}_2 : \tau$

How do we type locations?

References: Typing

Noticeable by its absence is a typing rule for location values. What is the type of a location value ℓ ? Clearly, it should be of type τ ref, where τ is the type of the value contained in location ℓ . But how do we know what value is contained in location ℓ ? We could directly examine the store, but that would be inefficient. In addition, examining the store directly may not give us a conclusive answer! Consider, for example, a store σ and location ℓ where $\sigma(\ell) = \ell$; what is the type of ℓ ?

Instead, we introduce *store typings* to track the types of values stored in locations. Store typings are partial functions from locations to types. We use metavariable Σ to range over store typings. Our typing relation now becomes a relation over 4 entities: typing contexts, store typings, expressions, and types. We write $\Gamma, \Sigma \vdash e : \tau$ when expression e has type τ under typing context Γ and store typing Σ

References: Typing

$$\frac{\Gamma, \Sigma \vdash e:\tau}{\Gamma, \Sigma \vdash ref \ e:\tau \ ref} \qquad \frac{\Gamma, \Sigma \vdash e:\tau \ ref}{\Gamma, \Sigma \vdash !e:\tau} \\
\frac{\Gamma, \Sigma \vdash e_1:\tau \ ref}{\Gamma, \Sigma \vdash e_1:\tau \ ref} \quad \frac{\Gamma, \Sigma \vdash e_2:\tau}{\Gamma, \Sigma \vdash e_2:\tau} \\
\frac{\Gamma, \Sigma \vdash \ell:\tau \ ref}{\Gamma, \Sigma \vdash \ell:\tau \ ref} \Sigma(\ell) = \tau$$

References: Soundness?

So, how do we state type soundness? Our type soundness theorem for simply-typed lambda calculus said that if $\Gamma \vdash e : \tau$ and $e \longrightarrow^* e'$ then e' is not stuck. But our operational semantics for references now has a store, and our typing judgment now has a store typing in addition to a typing context. We need to adapt the definition of type soundness appropriately. To do so, we define what it means for a store to be well-typed with respect to a typing context.

References: Soundness Aux. Def.

Store σ is *well-typed* with respect to typing context Γ and store typing Σ , written $\Gamma, \Sigma \vdash \sigma$, if dom $(\sigma) = dom(\Sigma)$ and for all $\ell \in dom(\sigma)$ we have $\Gamma, \Sigma \vdash \sigma(\ell) : \tau$ where $\Sigma(\ell) = \tau$.

References: Soundness Theorem

If
$$\emptyset, \Sigma \vdash e : \tau$$
 and $\emptyset, \Sigma \vdash \sigma$ and
 $< e, \sigma > \longrightarrow^* < e', \sigma' >$ then either e' is a value, or
there exists e'' and σ'' such that
 $< e', \sigma' > \longrightarrow < e'', \sigma'' >$.

References: Soundness

We can prove type soundness for our language using the same strategy as for the simply-typed lambda calculus: we use preservation and progress. The progress lemma can be easily adapted for the semantics and type system for references. Adapting preservation is a little more involved, since we need to describe how the store typing changes as the store evolves. The rule ALLOC extends the store σ with a fresh location ℓ , producing store σ' . Since $dom(\Sigma) = dom(\sigma) \neq dom(\sigma')$, it means that we will not have σ' well-typed with respect to typing store Σ .

References: Soundness

Since the store can increase in size during the evaluation of the program, we also need to allow the store typing to grow as well.

References: Preservation Lemma

If $\emptyset, \Sigma \vdash e : \tau$ and $\emptyset, \Sigma \vdash \sigma$ and $\langle e, \sigma \rangle \longrightarrow \langle e', \sigma' \rangle$ then there exists some $\Sigma' \supseteq \Sigma$ such that $\emptyset, \Sigma' \vdash e' : \tau$ and $\emptyset, \Sigma' \vdash \sigma'$.
