IMP: a simple imperative language

Lecture 5

Tuesday, February 5, 2024

We shall now consider a more realistic programming language, one where we can assign values to variables and execute control constructs such as if and while. The syntax for this simple imperative language, called IMP, is as follows:

		\mid while b do c
		\mid if b then c_1 else c_2
commands	$c\in\mathbf{Com}$	$c ::= skip \mid x := a \mid c_1; c_2$
boolean expressions	$b\in \mathbf{Bexp}$	$b ::=$ true false $a_1 < a_2$
arithmetic expressions	$a \in \mathbf{Aexp}$	$a ::= x \mid n \mid a_1 + a_2 \mid a_1 \times a_2$

1 Small-step operational semantics

We'll first give a small-step operational semantics for IMP. The configurations in this language are of the form $\langle c, \sigma \rangle$, $\langle b, \sigma \rangle$, and $\langle a, \sigma \rangle$, where σ is a store. The final configurations are of the form $\langle skip, \sigma \rangle$, $\langle true, \sigma \rangle$, $\langle false, \sigma \rangle$, and $\langle n, \sigma \rangle$. There are three different small-step operational semantics relations, one each for commands, boolean expressions, and arithmetic expressions.

 $\longrightarrow_{Com} \subseteq Com \times Store \times Com \times Store$ $\longrightarrow_{Bexp} \subseteq Bexp \times Store \times Bexp \times Store$ $\longrightarrow_{Aexp} \subseteq Aexp \times Store \times Aexp \times Store$

For brevity, we will overload the symbol \rightarrow and use it to refer to all of these relations. Which relation is being used will be clear from context.

The evaluation rules for arithmetic and boolean expressions are similar to the ones we've seen before. However, note that since the arithmetic expressions no longer contain assignment, arithmetic and boolean expressions can not update the store.

Arithmetic expressions

$$\frac{\langle a_1, \sigma \rangle \longrightarrow \langle a'_1, \sigma \rangle}{\langle a_1 + a_2, \sigma \rangle \longrightarrow \langle a'_1 + a_2, \sigma \rangle} \qquad \frac{\langle a_2, \sigma \rangle \longrightarrow \langle a'_2, \sigma \rangle}{\langle n + a_2, \sigma \rangle \longrightarrow \langle n + a'_2, \sigma \rangle} \qquad \frac{\langle n + m, \sigma \rangle \longrightarrow \langle p, \sigma \rangle}{\langle n + m, \sigma \rangle \longrightarrow \langle p, \sigma \rangle} \text{ where } p = n + m$$

$$\frac{\langle a_1, \sigma \rangle \longrightarrow \langle a'_1, \sigma \rangle}{\langle a_1 \times a_2, \sigma \rangle \longrightarrow \langle a'_2, \sigma \rangle} \qquad \frac{\langle a_2, \sigma \rangle \longrightarrow \langle a'_2, \sigma \rangle}{\langle n \times a_2, \sigma \rangle \longrightarrow \langle n \times a'_2, \sigma \rangle} \qquad \frac{\langle n \times m, \sigma \rangle \longrightarrow \langle p, \sigma \rangle}{\langle n \times m, \sigma \rangle \longrightarrow \langle p, \sigma \rangle} \text{ where } p = n \times m$$

 $\langle x,\sigma
angle\longrightarrow \langle n,\sigma
angle$ where $n=\sigma(x)$

Boolean expressions

$$\begin{array}{c} \langle a_1, \sigma \rangle \longrightarrow \langle a'_1, \sigma \rangle \\ \hline \langle a_1 < a_2, \sigma \rangle \longrightarrow \langle a'_1 < a_2, \sigma \rangle \\ \hline \end{array} \qquad \begin{array}{c} \langle a_2, \sigma \rangle \longrightarrow \langle a'_2, \sigma \rangle \\ \hline \langle n < a_2, \sigma \rangle \longrightarrow \langle n < a'_2, \sigma \rangle \\ \hline \end{array}$$

$$\overline{\langle n < m, \sigma \rangle \longrightarrow \langle \mathbf{true}, \sigma \rangle} \text{ where } n < m \qquad \qquad \overline{\langle n < m, \sigma \rangle \longrightarrow \langle \mathbf{false}, \sigma \rangle} \text{ where } n \geq m$$

Commands

$$\begin{array}{c} \langle a, \sigma \rangle \longrightarrow \langle a', \sigma \rangle \\ \hline \langle x := a, \sigma \rangle \longrightarrow \langle x := a', \sigma \rangle \end{array} \end{array}$$

$$\begin{array}{c} \langle c_1, \sigma \rangle \longrightarrow \langle c'_1, \sigma' \rangle \\ \hline \langle c_1; c_2, \sigma \rangle \longrightarrow \langle c'_1; c_2, \sigma' \rangle \end{array} \end{array}$$

For if commands, we gradually reduce the test until we get either true or false; then, we execute the appropriate branch:

$$\frac{\langle b, \sigma \rangle \longrightarrow \langle b', \sigma \rangle}{\langle \text{if } b \text{ then } c_1 \text{ else } c_2, \sigma \rangle \longrightarrow \langle \text{if } b' \text{ then } c_1 \text{ else } c_2, \sigma \rangle}$$

 $\langle \text{if true then } c_1 \text{ else } c_2, \sigma \rangle \longrightarrow \langle c_1, \sigma \rangle$ $\langle \text{if false then } c_1 \text{ else } c_2, \sigma \rangle \longrightarrow \langle c_2, \sigma \rangle$

_

For while loops, the above strategy doesn't work (why?). Instead, we use the following rule, which can be thought of as "unrolling" the loop, one iteration at a time.

(while *b* do *c*, σ) \longrightarrow (if *b* then (*c*; while *b* do *c*) else skip, σ)

We can now take a concrete program and see how it executes under the above rules. Consider we start with state σ where $\sigma(foo) = 0$ and we execute the program

The execution works as follows:

 $\langle \mathsf{foo} := 3; \mathsf{while} \mathsf{foo} < 4 \mathsf{ do} \mathsf{ foo} := \mathsf{foo} + 5, \sigma \rangle$ \rightarrow (**skip**; **while** foo < 4 **do** foo := foo + 5, σ') where $\sigma' = \sigma[\mathsf{foo} \mapsto 3]$ \longrightarrow (while foo < 4 do foo := foo + 5, σ') \rightarrow (if foo < 4 then (foo := foo + 5; W) else skip, σ') \longrightarrow (if 3 < 4 then (foo := foo + 5; W) else skip, σ') \longrightarrow (if true then (foo := foo + 5; W) else skip, σ') \rightarrow (foo := foo + 5; while foo < 4 do foo := foo + 5, σ') \longrightarrow (foo := 3 + 5; while foo < 4 do foo := foo + 5, σ') \rightarrow (foo := 8; while foo < 4 do foo := foo + 5, σ') \rightarrow (**skip**; **while** foo < 4 **do** foo := foo + 5, σ'') where $\sigma'' = \sigma'[\mathsf{foo} \mapsto 8]$ \longrightarrow (while foo < 4 do foo := foo + 5, σ'') \longrightarrow (if foo < 4 then (foo := foo + 5; W) else skip, σ'') \longrightarrow (if 8 < 4 then (foo := foo + 5; W) else skip, σ'') \longrightarrow (if false then (foo := foo + 5; W) else skip, σ'') $\longrightarrow \langle \mathbf{skip}, \sigma'' \rangle$

(where *W* is an abbreviation for the while loop **while** foo < 4 **do** foo := foo + 5).

2 Large-step operational semantics for IMP

We define large-step evaluation relations for arithmetic expressions, boolean expressions, and commands. The relation for arithmetic expressions relates an arithmetic expression and store to the integer value that the expression evaluates to. For boolean expressions, the final value is in **Bool** = {**true**, **false**}. For commands, the final value is a store.

$$\begin{split} & \Downarrow_{Aexp} \subseteq Aexp \times Store \times Int \\ & \Downarrow_{Bexp} \subseteq Bexp \times Store \times Bool \\ & \Downarrow_{Com} \subseteq Com \times Store \times Store \end{split}$$

Again, we overload the symbol \Downarrow and use it for any of these three relations; which relation is intended will be clear from context. We also use infix notation, for example writing $\langle c, \sigma \rangle \Downarrow \sigma'$ if $(c, \sigma, \sigma') \in \Downarrow_{Com}$. Arithmetic expressions.

$$\langle n,\sigma
angle \Downarrow n$$

$$\overline{\langle x,\sigma \rangle \Downarrow n}$$
 where $\sigma(x) = n$

$$\frac{\langle a_1, \sigma \rangle \Downarrow n_1 \qquad \langle a_2, \sigma \rangle \Downarrow n_2}{\langle a_1 + a_2, \sigma \rangle \Downarrow n} \text{ where } n = n_1 + n_2 \qquad \frac{\langle a_1, \sigma \rangle \Downarrow n_1 \qquad \langle a_2, \sigma \rangle \Downarrow n_2}{\langle a_1 \times a_2, \sigma \rangle \Downarrow n} \text{ where } n = n_1 \times n_2$$

Boolean expressions.

 $\langle \mathsf{true}, \sigma \rangle \Downarrow \mathsf{true}$

$$\langle \mathsf{false}, \sigma \rangle \Downarrow \mathsf{false}$$

$$\frac{\langle a_1, \sigma \rangle \Downarrow n_1}{\langle a_1 < a_2, \sigma \rangle \Downarrow \mathsf{true}} \text{ where } n_1 < n_2 \qquad \qquad \frac{\langle a_1, \sigma \rangle \Downarrow n_1}{\langle a_1 < a_2, \sigma \rangle \Downarrow \mathsf{true}} \text{ where } n_1 < n_2$$

Commands.

$$\mathsf{SKIP} \underbrace{\langle \mathsf{skip}, \sigma \rangle \Downarrow \sigma}_{\langle \mathsf{skip}, \sigma \rangle \Downarrow \sigma} \qquad \mathsf{ASG} \underbrace{\frac{\langle a, \sigma \rangle \Downarrow n}{\langle x := a, \sigma \rangle \Downarrow \sigma[x \mapsto n]}}_{\langle x := a, \sigma \rangle \Downarrow \sigma[x \mapsto n]} \qquad \mathsf{SEQ} \underbrace{\frac{\langle c_1, \sigma \rangle \Downarrow \sigma' \quad \langle c_2, \sigma' \rangle \Downarrow \sigma''}_{\langle c_1; c_2, \sigma \rangle \Downarrow \sigma''}}_{\langle c_1; c_2, \sigma \rangle \Downarrow \sigma''}$$

$$\operatorname{IF-T} \frac{\langle b, \sigma \rangle \Downarrow \operatorname{true} \quad \langle c_1, \sigma \rangle \Downarrow \sigma'}{\langle \operatorname{if} b \operatorname{ then} c_1 \operatorname{ else} c_2, \sigma \rangle \Downarrow \sigma'} \qquad \qquad \operatorname{IF-F} \frac{\langle b, \sigma \rangle \Downarrow \operatorname{false} \quad \langle c_2, \sigma \rangle \Downarrow \sigma'}{\langle \operatorname{if} b \operatorname{ then} c_1 \operatorname{ else} c_2, \sigma \rangle \Downarrow \sigma'}$$

It's interesting to see that the rule for while loops does not rely on using an if command (as we needed in the case of small-step semantics). Why does this rule work?

2.1 Command equivalence

The small-step operational semantics suggest that the loop **while** b **do** c should be equivalent to the command **if** b **then** (c; **while** b **do** c) **else skip**. Can we show that this indeed the case when the language is defined using the above large-step evaluation?

First, we need to to be more precise about what "equivalent commands" mean. Our formal model allows us to define this concept using large-step evaluations as follows. (One can write a similar definition using \rightarrow^* in small-step semantics.)

Definition (Equivalence of commands). Two commands c and c' are equivalent (written $c \sim c'$) if, for any stores σ and σ' , we have

$$\langle c, \sigma \rangle \Downarrow \sigma' \iff \langle c', \sigma \rangle \Downarrow \sigma'.$$

We can now state and prove the claim that while b do c and if b then (c; while b do c) else skip are equivalent.

Theorem. For all $b \in Bexp$ and $c \in Com$ we have

while *b* do $c \sim$ if *b* then (*c*; while *b* do *c*) else skip.

Proof. Let *W* be an abbreviation for **while** *b* **do** *c*. We want to show that for all stores σ , σ' , we have:

 $\langle W, \sigma \rangle \Downarrow \sigma'$ if and only if $\langle \text{if } b \text{ then } (c; W) \text{ else skip}, \sigma \rangle \Downarrow \sigma'$

For this, we must show that both directions (\implies and \iff) hold. We'll show only direction \implies ; the other is similar.

Assume that σ and σ' are stores such that $\langle W, \sigma \rangle \Downarrow \sigma'$. It means that there is some derivation that proves for this fact. Inspecting the evaluation rules, we see that there are two possible rules whose conclusions match this fact: WHILE-F and WHILE-T. We analyze each of them in turn.

• WHILE-F. The derivation must look like the following.

$$\mathsf{W}\mathsf{HILE}\mathsf{-}\mathsf{F}\frac{\overbrace{\langle b,\sigma\rangle\Downarrow}\mathsf{false}}{\langle W,\sigma\rangle\Downarrow\sigma}$$

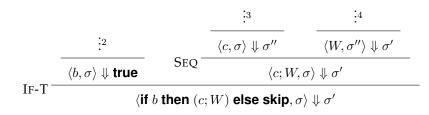

Here, we use :¹ to refer to the derivation of $\langle b, \sigma \rangle \Downarrow$ **false**. Note that in this case, $\sigma' = \sigma$.

We can use $:^1$ to derive a proof tree showing that the evaluation of **if** *b* **then** (*c*; *W*) **else skip** yields the same final state σ :

$$\begin{array}{c} \vdots \\ \hline \hline \langle b, \sigma \rangle \Downarrow \text{ false } \\ \hline \text{IF-F} \end{array} \begin{array}{c} S & \\ \hline \langle \text{skip}, \sigma \rangle \Downarrow \sigma \\ \hline \hline \langle \text{if } b \text{ then } (c; W) \text{ else skip}, \sigma \rangle \Downarrow \sigma \end{array}$$

• WHILE-T. In this case, the derivation has the following form.

We can use subderivations $:^2$, $:^3$, and $:^4$ to show that the evaluation of **if** *b* **then** (*c*; *W*) **else skip** yields the same final state σ .

Hence, we showed that in each of the two possible cases, the command if *b* then (c; W) else skip evaluates to the same final state as the command *W*.
